(57) **ABSTRACT**

Escutcheons for a temperature-controlled food holding cabinet are removable and field replaceable by the use of interlocking keys and keyholes that hold the escutcheon in place and align the escutcheon to electrical connectors. The escutcheons are provided with illuminated user interfaces. A key formed on either the escutcheon or chassis of the cabinet, engages a corresponding keyhole formed on either the cabinet chassis or the escutcheon.

UNIVERSAL FOOD HOLDING CABINET WITH BUTTONED-IN ESCUTCHEONS

BACKGROUND

Many restaurants' success depends on how quickly customers can be served with food items that a customer orders. If the rate at which a restaurant cooks food products equals the rate at which those same food products are being ordered and sold, a fast food restaurant can theoretically have freshly-cooked foods ready to serve for customers as they arrive. Since it is not always possible to match cooked-food production with customer ordering rates, and since fast food restaurant customers expect to receive their ordered food items quickly, many fast food restaurants pre-cook various food items and keep them warm, ready for sale until a customer arrives and purchases a pre-cooked food item.

Pre-cooked food items cannot be stored for prolonged periods and should be kept warm while they are being held. Prolonged heating causes food texture and flavor to deteriorate. The time that a food product can be kept warm yet remain palatable will vary with each type of food product. It is therefore beneficial to have an ability to store different types of foods at different temperatures and keep track of the time that a food has been kept warm.

Food holding cabinets are well known in the prior art. A problem with prior art food holding cabinets, as with most commercial restaurant equipment is that they sometimes fail and require a service technician to repair. In keeping with food service operators' goal of reducing cost, it would be desirable to provide on-site serviceability to a food holding cabinet whereby repairs can be effectuated by a restaurant operator, on-site and without having to call a service technician.

BRIEF DESCRIPTIONS OF THE DRAWINGS

Preferred embodiments are set forth in the following detailed description and accompanying drawings in which like reference numerals represent like parts.

FIG. 1 is a perspective view of a temperature controlled food holding cabinet with buttoned-in escutcheons;

FIG. 2 is a front elevation of the temperature controlled food holding cabinet shown in FIG. 1;

FIG. 3 is a first isolated perspective view of one compartment of the cabinet shown in FIG. 1;

FIG. 4 is a second isolated view of one compartment of the cabinet depicted in FIG. 1;

FIG. 5A is an isolated view of the front face or surface of a buttoned-in escutcheon;

FIG. 5B is an exploded view of the escutcheon shown in FIG. 5A;

FIG. 6 is a left-hand side view of the escutcheon;

FIG. 7 is an isolated view of the escutcheon attachment key shown in FIG. 6;

FIG. 8 is an isolated view of the back side of the left-hand end of the escutcheon;

FIG. 9 is an isolated view of the back side of the right-hand end of the escutcheon; and

FIG. 10 is an isolated view of the cabinet with the right side removed to show electronic circuit boards having electronic components.

DETAILED DESCRIPTION

FIG. 1 is a perspective view of a temperature controlled food holding cabinet 100. The cabinet 100 is comprised of a

2

top panel 102, a bottom panel 104, a left side panel 106 and a right side panel 108. The cabinet 100 also has a front side 110 and a rear side not visible in FIG. 1.

The top 102, bottom 104, left side 106 and the right side 108 comprise the chassis of the cabinet 100. "Chassis" and "cabinet" are used interchangeably.

The front side 100 (and rear side as well) has several substantially rectangular openings 114 into corresponding temperature-controlled food holding compartments 116. Food items, not shown, can be placed into the compartments 116 through the openings 114. Once a food item is placed inside the compartment 116, the temperature of a food item therein can be maintained relatively constant.

FIG. 2 is a front elevation view of the food holding cabinet 100. A control panel 200 provides a user interface. The control panel 200 includes a display panel 202 on which messages and status information is displayed. The display panel 202 is typically embodied as a liquid crystal display (LCD) panel, a light emitting diode (LED) panel or a plasma display panel.

A key pad 204 with pushbuttons and switches 206A and 206B enable a user to make various operational changes, such as specifying one or more temperatures for the different compartments 116. An on/off switch 207 located in the upper left hand corner 209 of the cabinet 100 enables the cabinet 100 to be turned on and off.

Each opening 114 into a heated compartment 116 is bounded on three sides by a buttoned-in escutcheon 210, the shape of which is reminiscent of an inverted Arabic letter "U." In FIG. 2, the escutcheon 210 for the top or upper-most compartment 116 is shown as having been removed.

The shape of the escutcheon 210 is also reminiscent of the shape of the symbol for pi, or π . Each escutcheon 210 has an elongated top portion 216 at the ends of which are two, downwardly-extending legs 208. FIG. 5A is a front perspective view of one escutcheon 210.

The left side 106 and the right side 108 of the cabinet 100 have elongated, upright covers 308 which enclose electrical connectors on the left and right ends of the escutcheons 210 and which "lock" the escutcheons 210 in place by virtue of the attachment of the covers 308 to the cabinet 100. The elongated covers 308 are formed with tabs 310 at the top end of the cover 308. The tab 310 is bent and extends through a mating slot 312 formed into a mounting flange that extends from the left and right sides but which is not visible in FIG. 2. A machine screw 314 at the bottom of the cover mates with a threaded hole in a second flange that extends from the chassis. Each cover 308 can thus be from the cabinet 100 and the escutcheons 210 removed by the removal of two machine screws 314. Stated another way, removing the escutcheons 210 requires only a screwdriver.

A heated compartment 116 is defined as the space between a substantially planar, electrically heated shelf 117 that also defines the bottom of a compartment 116 and, a substantially planar and optionally heated separation plate 119 that defines the top of a compartment. The holding cabinet 100 shown in FIG. 2 has five separate temperature-controlled compartments each of which is identified by the same reference numeral 116, however, an escutcheon 210 is applied to only the lower four temperature-controlled compartments 116. As stated above, the escutcheon 210 around the top compartment is shown in FIG. 2 as having been removed.

The top-most compartment 116, is shown with the escutcheon 210 removed in order to show a relatively thin, sheet metal flange 212 to which the escutcheons 210 are attached

3

using interlocking keys and keyholes that are described below. A flange **212** visible in FIG. 2 is thus behind each escutcheon **210**.

The flange **212** extends across the front **110** of the cabinet **100**, i.e., between the left side **106** and right side **108** of the chassis. As shown in the figures, the flange **212** is formed with three, spaced-apart keyholes **214**, however, alternate embodiments of the cabinet **100** have flanges **212** that have one keyhole, two keyholes, or four or more keyholes **214**. The flange **212** thus provides a structure to which the escutcheon **210** is attached but it also provides a structure that encloses or seals the space between the shelves **117** that defines a heated surface on which food products or food product packing rests in a compartment **116** and a shelf separation plate **119** that defines the top of each compartment **116**.

The left side of FIG. 6 shows the flange **212** in cross section and installed between a shelf **117** and a separation plate **199**. The left side of FIG. 6 also shows electrically resistive wire heating elements **608** attached to the shelf **117** and separation plate **199** and located in the space **610** between the shelf **117** and separation plate **199**.

Still referring to FIG. 6, the flange **212** is sized and arranged to provide a liquid-tight seal between the shelf **117** and plate **199** and thus enclose the space **610** between the shelf **117** and separation plate **119**. Grease and other liquids are thus prevented from flowing into the space **610** between the shelf **117** and separation plate **119** where wire heating elements **608** that make thermal contact with the shelf **117** are located. An optional heating element **608** also makes thermal contact with the separation plate **199** to provide heat from the top of the compartment **116**.

The flange **212** is sized, shaped and arranged to protrude outwardly from the front edges of the shelf **117** and separation plate **119**. In an alternate embodiment, the flange **212** is flush with the shelf **117** and separation plate **119**. In yet another embodiment, the flange **212** is recessed into the open space **610**. In FIG. 6, the flange has a cross sectional shape that conforms to an indentation **604** on the back side of the escutcheon. The slight curvature of both structures adds structural rigidity to both.

Referring now to FIG. 2 and FIG. 3, the keyholes **214** in the flange **210** are considered herein to be comprised of two parts or sections. The first section of the keyhole **214** is a substantially circular hole **216** that extends completely through the flange **212**. The second section of the keyhole **214** is an elongated slot portion **218** that is also formed completely through the material from which the flange **212** is made. The second "slot" portion **218** has a length that extends in a direction orthogonal to the sides **106** and **108** of the cabinet **100**. The slot portion **218** "opens into" the first section **216**. The second slot portion **218** (also referred to as a slot) is considered herein to extend laterally or sideways from the first circular portion **216**.

The slot portion **218** has a length, which is considered herein to be the distance or length that the slot **218** extends laterally from the edge of the circular portion **216** to the terminal end of the slot **218**, i.e., the end farthest from the first portion **214**. The slot portion **218** also has a width, which is considered herein to be the dimension of the slot **218** orthogonal to the length. The keyholes **214** receive mating locking keys on the back or rear surface of each escutcheon **210**. Insertion of the keys into the key holes and the translation of the keys in the slotted portion of the key holes is considered herein to be somewhat analogous or similar to the attachment of a button through a button hole. The escutcheon **210** is thus considered to be buttoned to the holding cabinet.

4

Best seen in FIG. 5A, but also visible in FIG. 2 is that the elongated top portion **502** of each escutcheon **210** has display panels **220** on which food information or heating/cooking information is displayed. A pushbutton or other input device **222** is located adjacent to each display panel **220** and provides a control input.

FIG. 3 is an isolated perspective view of the top-most compartment **116** of the cabinet **100** depicted in FIG. 1 and showing more clearly, the flange **212** and the keyholes **214** formed therein. It also shows the front edge of the separation plate **119** and the top surface of the shelf **117**. FIG. 3 also shows the inside, left-hand side wall **302** of the top-most holding compartment **116** and the bottom **304** of the same compartment **116**. Also shown in FIG. 3 is the elongated top portion **226** of the escutcheon **210** immediately below the top-most compartment **116** and which is attached to a flange not visible in the figure because the escutcheon **210** is attached to the flange by the inter-locking engagement of keys and keyholes described below. The keyholes **214** can be seen in FIG. 3 as having a circular first portion **216** and an elongated slot portion **218**. Three keyholes **214** are formed into the flange **212**.

FIG. 4 is another view of the top-most compartment **116** of the cabinet **100** depicted in FIG. 1 showing the back side **404** of escutcheon **210** for the same, top-most compartment **116**. The escutcheon is shown removed and facing downwardly to expose the back or rear face **404** of the escutcheon **210**. Three spaced-apart keys **402** extend away from the back face **404** of the elongated top portion **216** of the escutcheon. FIG. 4 also shows an electrical connector **406** facing outwardly from the back side **404** of the escutcheon. The connector **406** in FIG. 4 is located at the upper right-hand corner **408** of the escutcheon **210**.

FIG. 5A is an isolated view of the front face or surface of the escutcheon **210**. An elongated center portion **502** has downwardly-extending legs **504** at each end. Displays **220** and input controls **222** or switches are accessible to a user.

FIG. 5B is an exploded view of the escutcheon **210** shown in FIG. 5A. The escutcheon **210** is comprised of a front face **500** and a rear face **506**. The front face **500** has the aforementioned elongated horizontal first portion **502** and the aforementioned downwardly extending legs **504** at opposite ends of the horizontal first portion **502**. Elongated horizontal slots **503** are formed in the front face **500** and provide "windows" through which LEDs, liquid crystal display or plasma panels **508** mounted on a printed circuit board **510** can be seen. A plastic protective lens **512** is located in front of the circuit board **510** and held in place by a bezel **514**. Short, hollow cylinders **516** made of an opaque plastic fit around pushbutton switches **517** mounted on the circuit board **510**. Each cylinder **516** fits around one pushbutton switch **517** and around an array of light-emitting diodes **519** (one shown) mounted to the circuit board **510** such that the LEDs **519** are placed or located to "surround" the switches **517**. The cylinders **516** have a height selected to keep the bezel **514**, lens **512**, and circuit board **510** aligned with each other but to also allow the pushbutton switch **517** that it surrounds to be actuated by being depressed through a flexible, light-transmissive filter **521** in the front face **500**, i.e., flexible enough to facilitate actuation of the switch **517** that is located behind each filter **521**. The opaque cylinders **516**, LEDs **519** and transmissive filters **521** provide an illuminated indicator for a switch **517**.

The transmissive filters **521** and cylinders **516** provide a lighted annulus **523** around the switch **517**. The filters **521** and cylinders **516** are therefore sized, shaped and arranged to be light transmissive in such a way that a ring or annulus **523** of light is made to appear around the switch **517**. Stated

5

another way, the light-transmissive portion of a transmissive filter **521** is ring-shaped or annulus-shaped **523** and with an outside diameter relative to the inside diameter of the cylinder **516** such that an annular-shaped light **523** appears to be emitted around the switch **517**. In alternate embodiments, the transmissive filters **521** have light-transmissive filters that are lighted dots or lighted arcs of a circle instead of ring-shaped or annular.

In one embodiment, four monochromatic LEDs are wired into the circuit board **510** and evenly distributed around a switch to provide a virtually continuous ring of light, i.e., a light that appears to be smooth and continuous and not from discrete points of light from separate LEDs. When used with monochromatic LEDs, a white filter **521** thus provides a monochromatic light around the filter **521** (annular) to identify where an operator should exert pressure on the filter **521** in order to actuate the switch **519** behind the filter **521**.

In another embodiment, one or more monochromatic LEDs of a first color are wired into the circuit board **510**, evenly distributed around a switch **519** and within a cylinder **516** made of an opaque plastic. One or more monochromatic LEDs of a second color are also wired into the circuit board **510**, evenly distributed around the same switch **519** and within the same cylinder **516**. By selectively activating LEDs of the first color and second color, a white filter **521** provides an indicator light around the filter **521** that can be two or three different colors by selectively activating the first and second colored LEDs or by activating both sets of LEDs at the same time.

In yet another embodiment, one or more red LEDs are wired into the circuit board **510**, evenly distributed around a switch **519** and within a cylinder **516** made of an opaque plastic. One or more green LEDs are also wired into the circuit board **510**, evenly distributed around the same switch **519** and within the same cylinder **516**. One or more blue LEDs are also wired into the circuit board **510**, evenly distributed around the same switch **519** and within the same cylinder **516**. By selectively activating the red, green and blue LEDs, a white filter **521** provides an indicator light around the filter **521** that can display virtually any color, depending on how the colors are blended by the selective activation of red, green and blue LEDs and the selective control of the light level produced by each of them.

Mating tabs in the shape of bulbous protuberance formed in the rear portion **506** of the escutcheon **210** and mating slots that are formed in the front portion **500** hold the pieces of the escutcheon together. Not visible in FIG. **5** are the bulbous-shaped “keys” that extend away from the rear portion **506** of the escutcheon. The “keys” are sized, shaped and arranged to fit into the first, circular portion **216** of a keyhole **214**. Once the key is fully inserted into the circular portion **216**, sliding or translating the key and keyhole sideways with respect to each other locks the key and keyhole together.

FIG. **6** is a left-hand side view of the escutcheon **210** showing the escutcheon **210** after the layers depicted in FIG. **5** are assembled together and depicting how the escutcheon meets the flange **212**. The front surface **500** is opposed by the rear surface **506**. One of the aforementioned locking keys **602** extends orthogonally away from the rear surface **506**. The face of a light-transmissive filter **521** behind which is a push-button switch **517** that is attached to the circuit board **510** inside the escutcheon **210**.

As was stated above, the flange **212** is sized and arranged to provide a liquid-tight seal between a heated shelf **117** and separation plate **199**. The flange **212** thus encloses the space **610** between the shelf **117** and separation plate **119**. Grease and other liquids are thus prevented from flowing into the

6

space **610** between the shelf **117** and separation plate **119** where wire heating elements **608** that make thermal contact with the shelf **117** are located. An optional heating element **608** also makes thermal contact with the separation plate **199** to provide heat from the top of the compartment **116**.

In FIG. **6**, the flange **212** is generally convex. It is sized, shaped and arranged to protrude outwardly from the front edges of the shelf **117** and separation plate **119** but it also conforms to a mating, concave-shaped curve **604** formed into the back side of the escutcheon. In an alternate embodiment, the flange **212** is flush with the shelf **117** and separation plate **119**. In yet another embodiment, the flange **212** is recessed into the open space **610**. In FIG. **6**, the flange has a cross sectional shape that conforms to an indentation **604** on the back side of the escutcheon. The slight curvature of both structures adds structural rigidity to both.

FIG. **7** is an isolated view of the bulbous key **602** shown in FIG. **6** protruding from the back side or face **506** of the escutcheon **210**. The key **602** is also referred to herein as a locking key. While the preferred embodiment of the key **602** is formed from the same material as the rear face **506**, i.e., during an injection molding process, the key is nevertheless considered herein to be comprised of two portions.

A first portion **702** of the key **602** is substantially columnar, i.e., its shape is reminiscent of a column. The first, columnar portion **702** has a bottom or first end **704** that meets the rear surface **506** of the escutcheon **210**. The first columnar portion **702** also has a second end **706** at which a bulbous second portion **708** is formed. The bulbous second part **708** has a tapered surface **710**, the cross-sectional shape of which is reminiscent of a funnel.

In a preferred embodiment, the bulbous second portion **708** has an outside diameter. The diameter of the bulbous portion is selected to be less than the inside diameter of the substantially circular first portion **216** of the aforementioned keyholes **214**. The bulbous second portion **708** will thus fit through the substantially circular first portion **216** of a keyhole **214** but not through the second slot portion **218** of a keyhole.

The columnar first portion **702** of the key **602** has an outside diameter selected to be less than the width of the second slot portion **218** of a keyhole. When the bulbous second portion **708** of the key **602** is fully inserted into the substantially circular portion **216** of a keyhole **214**, the entire key can and the escutcheon **210** to which it is attached can translate sideways, with the columnar portion **702** sliding in the slot portion **218** of the keyhole. Translating the key **602** sideways in a keyhole **214** to where the bulbous second portion **708** is “behind” the slot portion **218** will thus button or lock the key **602** into the keyhole **214**. The taper **710** on the bulbous second portion **708** is sized, shaped and arranged to provide a compressive force against the flange as the key **602** is slid laterally through the rectangular slot portion of the keyhole. Sideways translation of the key **602** in the keyhole removably attaches the escutcheon **210** to the flange when the escutcheon is slid in a first direction. Sliding the escutcheon sideways in the opposite direction allows the escutcheon to be removed from the flange. The assembly is pushed “in” or toward the cabinet **100** when sliding either to the left to insert or to the right to remove.

For completeness, FIG. **8** is an isolated view of the back side **506** of the left-hand end of the escutcheon **210**. FIG. **9** is an isolated view of the back side **506** of the right-hand end of the escutcheon **210**. As shown in FIG. **8** and FIG. **9**, both ends of the back side **506** of the escutcheon **210** are provided with electrical connectors **810**. The electrical connectors **810** pro-

7

vide an electrical interface between circuitry and displays of the escutcheon **210** that are shown in FIG. 5, and electronics within the cabinet **100**.

FIG. 10 is an isolated view of the cabinet **100** with the right side **108** removed to show electronic circuit boards **1002** having electronic components **1004** that control the cabinet **100**. The electrical connector **810** of the top-most escutcheon **210** is electrically connected via a ribbon cable **1006** to components **1004** mounted on a circuit board **1002**.

Those of ordinary skill in the art will recognize that the embodiments described above have the keyhole **214** formed as part of the flange **212**. Insertion of the bulbous portion of the key into the circular portion of a key hole followed by the lateral translation of the key in the key hole, made possible by sliding the columnar portion of the key sideways through the slot portion of a key hole, attaches the escutcheon to the flange. The action of attaching the escutcheon to the flange is analogous to the insertion of a button into a button hole. The escutcheon is thus considered to be "buttoned in" to the holding cabinet.

In a preferred embodiment, the keys **402**, which interlock with the keyholes **214** are formed as part of the escutcheon. In an alternate embodiment, the "location" of the keys and keyholes are reversed. The flange **212** is provided with keys that interlock with keyholes formed into the back sides of the escutcheons.

The escutcheon need not be U-shaped. In an alternate embodiment, the escutcheon does not have downwardly-extending legs at each end of the center portion **502**.

It will be apparent to those of ordinary skill that the escutcheon **212**, the key **402** and the keyhole **214** provide a food holding cabinet having escutcheons **210** that are field-removable, the removal of which requires little or no tools.

The foregoing description is for purposes of illustration only as the true scope of the invention is set forth by the appurtenant claims.

What is claimed is:

1. An escutcheon for a food holding cabinet, the escutcheon comprised of:

a center portion having front and rear surfaces and first and second opposing ends;

a key extending outwardly from the rear surface, the key being configured to fit into a mating key hole and thereby attach the escutcheon to the food holding cabinet; and

at least one of a user input device or a display housed within the center portion of the escutcheon and exposed through an opening in the front surface of the center portion of the escutcheon.

2. The escutcheon of claim 1, wherein at least one of the first and second opposing ends is provided with a leg, which is substantially orthogonal to the center portion.

3. The escutcheon of claim 1, wherein the key is comprised of first and second parts, the first part of the key being columnar with top and bottom ends, the first part of the key having a first outside diameter extending away from the rear surface of the escutcheon, the bottom end of the first part of the key being coupled to and beginning at the rear surface of the escutcheon, the second part of the key being bulbous and attached to the top end of the first part of the key, the second part of the key having a second outside diameter greater than the first outside diameter of the first part of the key.

4. The escutcheon of claim 2, wherein the key is configured to fit into a key hole comprised of a substantially circular first part and a substantially rectangular second part, which is joined with the substantially circular first part, the substantially circular first part of the key hole having a diameter selected to accept the bulbous second part of the key, the

8

substantially rectangular second part of the key hole having a length and a width, the width being selected to deny entry of the bulbous second part of the key into the rectangular second part and accept the outside diameter of the first part of the key.

5. The escutcheon of claim 4, wherein the key hole is formed in a flange attached to a food warming cabinet and wherein the key and key hole are configured to urge the escutcheon and the flange together as the first part of the key is moved away from the substantially circular part of the key hole, along the rectangular second part of the key hole.

6. The escutcheon of claim 1, wherein the user input device is comprised of a user interface.

7. The escutcheon of claim 6, wherein the user interface is comprised of at least one switch.

8. The escutcheon of claim 6, wherein the user interface is comprised of an illuminated switch.

9. The escutcheon of claim 8, wherein the illuminated switch is comprised of an annulus around the switch, the annulus being around a plurality of light emitting diodes.

10. The escutcheon of claim 6, wherein the user interface is comprised of a switch, at least partially illuminated by a multi-colored, annular-shaped light source, which provides an illuminated annulus around the switch.

11. The escutcheon of claim 10, wherein the multi-colored annular-shaped light source is comprised of a plurality of light emitting diodes.

12. The escutcheon of claim 10, wherein the multi-colored light source is comprised of a substantially opaque cylinder having first and second ends and a light filter, the cylinder surrounding the plurality of light emitting diodes at the first end, the light filter being proximate the second end;

whereby light from the light emitting diodes is emitted from the light filter.

13. The escutcheon of claim 1, comprising an electrical connector housed within the escutcheon and exposed through an opening in the rear surface of the center portion of the escutcheon, the electrical connector being configured to provide an electrical interface between circuitry in the food holding cabinet and the user input device or display.

14. A temperature-controlled food holding cabinet having at least one food holding compartment, the food holding cabinet comprised of:

a chassis having a flange adjacent to an opening into a temperature-controlled food holding compartment, the flange facing away from the cabinet and having a key hole formed therein; and

an escutcheon having:

a front surface;

a rear surface abutting the flange of the chassis;

a key extending outwardly from the rear surface, the key being inserted into the key hole, the key and key hole being configured to allow the escutcheon to be translated in a first direction to attach the escutcheon to the flange and translated in an opposite second direction to release the escutcheon from the flange; and

at least one of a user input device or a display housed within the escutcheon and exposed through an opening in the front surface of the escutcheon.

15. The temperature-controlled food holding cabinet of claim 14, wherein the user input device comprises an electrical user interface, which is electrically connected to circuitry within the chassis through a connector attached to the escutcheon.

16. The temperature-controlled food holding cabinet of claim 14, wherein the hole is comprised of a substantially circular part and an elongated slot part extending laterally away from the substantially circular part, the substantially

circular part of the hole having a first diameter, the elongated slot part of the hole having a length and a width, the length dimension being in a direction away from the substantially circular part of the hole, the first diameter of the substantially circular part of the hole being selected to receive a bulbous 5 first part of the key, the bulbous first part of the key having a second diameter less than the first diameter, the width of the elongated slot part of the hole being less than the first diameter and less than the second diameter.

17. The temperature-controlled food holding cabinet of 10 claim 14, the key including a first part and a second part, the first part of the key being columnar and having a first outside diameter, the first part of the key having a top end and a bottom end, the bottom end being attached to and beginning at the rear surface of the escutcheon, the first part of the key 15 extending away from the rear surface of the escutcheon such that the top end of the first part of the key is spaced apart from the rear surface of the escutcheon, the second part of the key being bulbous and attached to the top end of the first part of the key, the second part of the key having a second outside 20 diameter greater than the first outside diameter of the first part of the key.

18. The temperature-controlled food holding cabinet of claim 14, comprising an electrical connector housed within the escutcheon and exposed through an opening in the rear 25 surface of the escutcheon, the electrical connector being configured to provide an electrical interface between circuitry in the chassis and the user input device or display.
